## **DEVELOPMENT OF PRECISION POINTING CONTROLLERS WITH AND WITHOUT VIBRATION SUPPRESSION FOR THE NPS PRECISION POINTING HEXAPOD**

**Ronald M. Bishop, Jr.-Lieutenant Commander, United States Navy  
B.S., United States Naval Academy, 1991**

**Aeronautical and Astronautical Engineer-December 2002**

**Master of Science in Astronautical Engineering-December 2002**

**Advisor: Brij N. Agrawal, Department of Aeronautics and Astronautics**

**Second Reader: Hong-Jen Chen, National Research Council Research Associate**

Satellite optical payloads demand better vibration control and finer precision pointing than ever before. Fortunately, the Stewart-Gough platform offers the potential of accomplishing both of these simultaneously.

Using the Precision Pointing Hexapod at NPS (a Stewart-Gough platform), several controllers for precision pointing, with and without vibration disturbances, were developed. Unlike the traditional means of pointing a hexapod, (i.e. sensing and controlling strut length to orient payload), this research used the payload orientation derived from payload mounted position sensors to determine orientation and provide feedback to the actuator controller. Small and large angle controllers were developed and evaluated for accuracy using static pointing and dynamic tracking tasks. The pointing controllers were then added to an Adaptive Disturbance Canceller and evaluated for pointing accuracy and vibration suppression performance given a single tone disturbance.

The results showed a static pointing accuracy of  $\pm 0.008^\circ$  and a dynamic pointing accuracy ranging from  $\pm 0.05^\circ$  to  $\pm 0.2^\circ$ , depending on the size and speed of the circular trajectory. Vibration suppression down to the noise floor was achieved in all static orientations tested. As for dynamic circle-tracking performance, at least a 20 dB reduction in the fundamental disturbance was obtained without degradation in pointing accuracy.

## **DESIGN OF OPTIMAL CYCLERS USING SOLAR SAILS**

**Robert E. Stevens-Lieutenant Commander, United States Navy  
B.S., United States Naval Academy, 1989**

**Aeronautical and Astronautical Engineer-December 2002**

**Master of Science in Astronautical Engineering-December 2002**

**Advisor: I. M. Ross, Department of Aeronautics and Astronautics**

**Second Reader: Dennis V. Byrnes, Jet Propulsion Lab**

Ongoing interest in establishing a base on Mars has spurred a need for regular and repeated visits to the red planet using a cycling shuttle to transport supplies, equipment and to retrieve surface samples. This thesis presents an approach to designing an optimal heliocentric cycling orbit, or cycler, using solar sails. Results show that solar sails can be used to significantly reduce  $V_\infty$ s at Mars and Earth. For example, using a reasonably high performance solar sail, a  $V_\infty|_{Mars} = 2.5$  km/s is possible at every synodic period using a two-dimensional orbit model. Lower performance sails were also modeled resulting in paths that behaved more like a ballistic Aldrin cycler with higher  $V_\infty$ s. Double rendezvous missions were explored where the spacecraft must match the velocities of both Earth and Mars, offering promising trajectories for Mars sample return missions. The solutions to these missions, although not necessarily cyclers, show that using a sail to rendezvous with and remain near Mars for an optimal amount of time will minimize the total

transit time between Earth and Mars. General-purpose dynamic optimization software, DIDO, is used to solve the optimal control problem using a pseudospectral method using both two- and three-dimensional elliptic orbit models.

Although computer-processing power has increased dramatically over the past few decades, minimizing computation time is still critical when conducting numerical aerodynamic analyses. One area where this is evident is the grid generation routines used in most code for this area of research. While many more sophisticated grid generation techniques are available, algebraic grid generation is still in use today due strictly to efficiency. Computational efficiency is of particularly great concern during analyses that involve motion of the surface being analyzed, since computing a new grid at each time step is often required. Unfortunately however, few if any, algebraic grid generation routines exist that are powerful enough to produce a grid with no overlapping gridlines and minimal distortion, yet still minimize computation time. As a result, the purpose of this thesis was to design such a routine. The end result is a C-Grid generating routine with a Graphical User Interface (GUI) called Astro Grid.

## **FACE RECOGNITION USING INFRARED IMAGING**

**Diogo C. Pereira-First Lieutenant, Brazilian Air Force  
B.S.E.E., Instituto Tecnológico de Aeronautica, Brazil, 1994  
Electrical Engineer-December 2002**

**Master of Science in Electrical Engineering-December 2002**

**Thesis Supervisor: Monique P. Fargues, Department of Electrical and Computer Engineering**

**Thesis Co-Supervisor: Gamani Karunasiri, Department of Physics**

**Thesis Committee Member: Roberto Cristi, Department of Electrical and Computer Engineering**

This study investigated an infrared (IR) face recognition system using an uncooled IR camera. A computer-based image collection set-up was designed and used to create a small database of 420 facial images, from 14 volunteers. Manual and automated facial image cropping routines were implemented. Two linear approaches for the dataset dimension reduction and classification were implemented and their resulting classification performances compared: PCA-based and LDA approaches. Results show that the best PCA-based average classification performance is equal to 92.22% while the LDA-based classification performance is equal to 99.40%. These results successfully show that an uncooled IR camera may be used to discriminate between individual subjects obtained from a small database collected under a very controlled environment.

**Mechanical Engineer-December 2002**

**Master of Science in Mechanical Engineering-December 2002**

**Advisor: Anthony J. Healey, Department of Mechanical Engineering**

Recovery of Autonomous Underwater Vehicles (AUVs) can often be an autonomous operation itself. In the case of an AUV that is launched and recovered at some significant depth below the surface, the recovery platform to which the vehicle will dock is often not a stationary platform. The recovery cage/platform has dynamics associated with it which are induced by wave motion effects on the ship to which the cage is tethered. In order to successfully recover a vehicle into a cage platform it will be preferred for the vehicle to have the capability to compensate for this motion when making its final approach to the cage. Using active compensation, a smaller cage can be utilized for recovery of an AUV. This research attempts to investigate a means by which a vehicle may be made to track, in depth, dynamic motion with zero phase lag between the vehicle and the recovery platform utilizing an error space controller.
